Problem Sequence - Solutions

This document will be filled up with the solutions from the problem sequence.

Solution 1 *(Greg)*

From Axiom 1, there are three cases to consider:

1. $p = 0$

   p is equal to the only element of M. From the definition of limit point, every segment containing p must contain a point of M different from p. However, there are no points in M different from p, so p must not be a limit point of M.

2. $p > 0$

   From Axiom 3, there exists a point a such that $0 < a < p$. There also exists a point b such that $b > p$. Since $p > 0$ and $b > p$, Axiom 2 tells us that $b > 0$. We can then form the segment $S = (a, b)$. Since $a > 0$ and $b > 0$, 0 is not between a and b, so S does not contain 0. However, $a < p < b$, so S contains p. S is a segment containing p that does not contain any element of M, so p is not a limit point of M.

3. $p < 0$

   (symmetric to the $p > 0$ case)

Therefore, regardless of our choice of p, we can construct a segment that contradicts the requirements in the limit point definition, so p is not a limit point of M.

Solution 2 *(Jeff)*

According to Definition 4, we can prove that p is not a limit point of M if we can construct a segment containing p but not a different point of M. Construct this segment as follows:

1. *If all points of M are on the opposite side of p, choose any value as an endpoint.*

2. *If any point of M is on the same side of p, choose a point between the nearest point of M and p. (Axiom 3 confirms that there will be such a point.)*

This segment contains p but will not contain any points of M (with the exception of p, if p is 0 or 1). Therefore, we have found a segment that does not fulfill the requirements of Definition 4, so p is not a limit point of M.
